A theory of failure by creep-fatigue interaction

What is it about?

When a material is subjected to extreme working conditions under thermal-mechanical loads, creep and fatigue damage will occur, compounded with environmental effect, which affect the component life. This paper provides a framework—the integrated creep-fatigue theory (ICFT)—to integrate all the damage effects into one lifeing equation, which is generally valid to deal with engineering design problems against combination of creep, fatigue and thermomechanical fatigue failures.

Why is it important?

The ICFT is mathematically derived to describe the holistic damage accumulation process consisting of nucleation and propagation of surface or subsurface fatigue cracks in coexistence with heterogeneously distributed damage promoted by creep, leading to final fracture. This failure process is common to all metallic materials and occurs by well-recognized and quantifiable mechanisms. Therefore, ICFT is a generalized theory to deal with material failure problems in product design and maintenance. Besides, it is physics-based and connects to other metallurgical phenomena such as microstructural evolution, so it can evolve into an all-comprehending material behavior and failure theory.

Material fatigue and creep failure issues have been bothering people and therefore become subjects of studies for more than 100 years. It is time to take a holistic view of this matter. I hope this article makes general complicated material failure phenomena easier to understand and describe on a mechanism basis.
